LifeBook

Current data model — workable, with one honest gap flagged

Prepared by LifeBook Inc. • Version 4.0 • September 2026

Implemented today as a single JSON file, structured exactly as these tables — the field shapes are what a real Postgres/Firestore migration would inherit, not a simplified stand-in.

1. Identity

users / preferences

Field	Type	Notes
id (uid or deviceId)	string, PK	Real Firebase uid once Auth is configured, else anonymous local id
displayName / spiritualPath / dailyHabits / notificationTime	text / array	
onboardingCompletedAt	timestamp	

2. Mood & content

mood_checkins

Field	Type	Notes
id	uuid, PK	
deviceId	string, FK	
mood	text	grateful / peaceful / seeking / doubting / distant / convicted — unvalidated vocabulary, see PRD section 2
note	text, nullable	
createdAt	timestamp	

generated_content

Field	Type	Notes
id / checkinId	uuid	
verseText / verseReference	text	From the fixed, vetted corpus
whyThisVerse / meditation / reflectionQuestion / prayer / actionStep	text	
reviewVerdict	text	pass / uncertain — no human reviewer currently staffed to act on "uncertain"

3. Journeys

journeys / journey_days (static catalog) / user_journey_progress

Field	Type	Notes
recommendedMoods	array<text>	Drives the recommendation engine — mapping quality inherits the mood vocabulary's own unvalidated status
currentDay / completedDays / startedAt / completedAt	various	Per-user progress

4. Community, progress, library, subscription

Unchanged in shape from the prior revision — groups, prayer_requests, discussions, streaks, badges (computed, not stored), journal_entries, favorites, library_books, subscriptions. See the previous Backend Schema document for full field listings; nothing structural changed here in this revision.

5. Trust & safety

flags / push_tokens

The flags table works and is tested. It has no corresponding table or process for reviewer assignment, SLA, or resolution tracking — because no reviewer has been staffed yet (PRD, section 6). Adding that structure is premature until a person exists to use it.

6. A gap worth naming: no analytics/event schema exists

There is currently no table capturing screen views, flow-step completions, or drop-off points. This is not an oversight in this document — it reflects a real gap in the running system. A minimal events table (userId, eventName, screenName, timestamp, metadata) would be enough to start answering the validation questions raised throughout this revision, and should be considered part of the next concrete build task, not deferred indefinitely.
